GENERAL GUIDE

to

THE BRITISH MUSEUM
(NATURAL HISTORY).

HISTORICAL INTRODUCTION.

The British Museum dates its actual foundation from the year Foundation. 1753, when an Act of Parliament was passed "for the purchase of the Museum or Collection of Sir Hans Sloane, and of the Harleian Collection of Manuscripts, and for providing One General Repository for the better Reception and more convenient Use of the said Collections and of the Cottonian Library and of the Additions thereto."

Sir Hans Sloane, an eminent physician in London, was for sixteen years President of the Royal College of Physicians, and in 1727 succeeded Sir Isaac Newton in the Presidential Chair of the Royal Society. He had been throughout his long life a diligent and miscellaneous collector, having, as stated in the Preamble of the Act of Incorporation of the Museum, "through the course of many years, with great labour and expense, gathered together whatever could be procured, either in our own or foreign countries, that was rare and curious." His collection, which at the time of his death in 1753 was contained in his residence, the Manor House, Chelsea, consisted of "books, drawings, manuscripts, prints, medals and coins, ancient and modern antiquities, seals, cameos and intaglios, precious stones, agates, jaspers, vessels of agate and jasper, crystals, mathematical instruments, pictures, and other things," which latter included numerous zoological and geological speci-
mens, and an extensive herbarium of dried plants preserved in 310 large folio volumes.

According to the terms of Sir Hans Sloane's will, this collection was purchased for the sum of £20,000, far below its intrinsic value, in order "that it might be preserved and maintained, not only for the inspection and entertainment of the learned and the curious, but for the general use and benefit of the public to all posterity."

The valuable collection of manuscripts formed by Sir Robert Cotton at the end of the sixteenth and beginning of the seventeenth centuries, was already the property of the nation, having been presented by his grandson, Sir John Cotton, in the year 1700. The Harleian Collection was obtained by purchase at the same time as the Sloanian, and the three were brought together under the designation of "the British Museum," placed under the care of a body of trustees,* and lodged in Montagu House, Bloomsbury, purchased for their reception in 1754. They were opened to the public on the 15th of January, 1759. Admission to the galleries of antiquities and natural history was at first by ticket only on application in writing, and limited to ten persons, for each of three hours in the day. Visitors were not allowed to inspect the cases at their leisure, but were conducted through the galleries by officers of the house. The hours of admission were subsequently extended; but it was not until the year 1810 that the Museum was freely accessible to the general public for three days in the week, from ten to four o'clock. The present daily opening, with longer hours in summer, dates only from 1879.

At the time of the foundation of the Museum, the site allotted seemed amply sufficient for its purposes; but gradually, as the collections of all kinds increased, they outgrew the limits, not only of the original Montagu House, but even of its

* The Trustees under the Act of Incorporation were the Archbishop of Canterbury, the Lord Chancellor, the Speaker of the House of Commons, and seventeen principal Officers of State, for the time being; six representatives of Founders' families; the Presidents of the Royal Society and College of Physicians; and fifteen other Trustees to be elected by them. Subsequently, the Presidents of the Royal Academy of Arts and of the Society of Antiquaries, a Trustee by special nomination of the Sovereign, and three more family Trustees were added to the Board.
successor, the present classical building, completed in 1845 from the designs of Sir Robert Smirke. The erection of the magnificent reading-room in 1857 disposed for a time of the difficulty of finding accommodation for the ever-growing library; but the keepers of other departments continued urgent in their demands for more space, and after much discussion of rival plans for keeping the collections together and obtaining the needful extension of room by acquiring the property immediately around the old Museum, or for severing the collections and removing a portion to another building, the latter course was finally decided upon. At a special general meeting of the trustees, held on the 21st of January, 1860, attended by many members of the Government in their official capacity, a resolution moved by the First Lord of the Treasury was carried "That it is expedient that the Natural History Collection be removed from the British Museum, inasmuch as such an arrangement would be attended with considerably less expense than would be incurred by providing a sufficient additional space in immediate contiguity to the present building of the British Museum."

No immediate action was taken on this resolution. In order to obtain fuller assurance of the best methods of proceeding, a Select Committee of the House of Commons was appointed in the Session of the same year, 1860, with instructions to enquire how far, and in what way, it might be desirable to find increased space for the Museum collections. Their report, which was adverse to the decision of the general meeting of the Trustees of the 21st of January, stated "that sufficient reason has not been assigned for the removal of any part of the valuable collections now in the Museum, except that of Ethnography and the portraits and drawings," and suggested the purchase of the land and houses in the immediate vicinity of the old Museum as the best site for future extension.

The Trustees had no other course than to refer to the Government the final determination of the question; and in November, 1861, they received intimation from the Lords of the Treasury that they were prepared to take steps for removing a portion of the National Collection to South Kensington, and the Trustees were asked to give further advice in respect to this proposal.
Their recommendation was that the whole of the Natural History Collections should be simultaneously removed, as well as those of Ethnography. Accordingly a Bill was brought in by the Government early in the Session of 1862 to enable the Trustees to effect this removal; but it was rejected on the ground of the great outlay required for the erection of the proposed new building at South Kensington.

In the Session of 1863 the Government renewed their efforts to cope with the Museum difficulty, and after failing to induce the House of Commons to sanction the purchase of the entire Exhibition Buildings at South Kensington, with a view to appropriating a portion of them to the purpose of a Museum of Natural History, succeeded in obtaining a vote for the purchase of the requisite number of acres from the exhibition ground at the price of £10,000 per acre. The prospect of the immediate erection of the desired building seemed now sufficiently promising; but nearly twenty years were to elapse before its complete realisation. Plans of the proposed building had already been prepared for Government. In September, 1862, Mr. Hunt, of the Office of Works, was instructed to work out the design of a building suggested by Professor Owen, and this was submitted to the House of Commons in June, 1863. The proposed building was to have covered about four acres of land; would have consisted of a vaulted basement, two storeys above the roadway for the exhibition of the collections, with an attic over a part of the centre for libraries and professors' rooms, and would have included a theatre, 100 feet in diameter, for lectures. The site was to be on the east side of Queen's Gate, and the cost was estimated at £350,000.

In January, 1864, the Commissioners of Her Majesty's Works issued an advertisement for designs for a Natural History Museum and a Patent Museum, to be erected on part of the site of the International Exhibition at South Kensington, the plan prepared by Mr. Hunt in September, 1882, from Professor Owen's suggestions, being proposed as a model in respect to dimensions and internal arrangement.

The plans of the various competitors were submitted to Her Majesty's Commissioners of Works, who awarded prizes to three of the number, giving precedence to that of Captain Francis
Fowke, R.E., and then referred the three premiated plans to the Trustees of the British Museum. As the internal arrangements in Captain Fowke's plan did not meet with the approval of the Museum officers, he was desired to modify them in conformity with the requirements of the Trustees. He was engaged in this labour when his death occurred, in September, 1865.

Early in the year 1866, Mr. Alfred Waterhouse was invited by the Chief Commissioner of Works to take up the unfinished work of Captain Fowke; but he found himself unable to complete the plan to his own satisfaction, and in February, 1868, he was commissioned to form a fresh design, embodying the requirements of the officers of the Natural History Departments of the Museum.

Mr. Waterhouse was not long in submitting to the Trustees his plan and model of the building, with a disposition of galleries as required, and these were formally accepted by the Trustees in April, 1868. It was not, however, until February, 1871, that the working plans had been thoroughly considered, and received the final approval of the Trustees.

The actual work of erection was commenced in the year 1873, and the building was handed over to the Trustees of the British Museum by Her Majesty's Commissioner of Works in the month of June, 1880. Immediately that the exhibition cases were completed, and the galleries were sufficiently dry to receive the collections, the great labour of removing the Natural History Collection from Bloomsbury was commenced. The departments of Geology, Mineralogy and Botany, were arranged in their respective sections of the Museum in the course of the year 1880, and the portion of the Museum which contained these departments was first opened to the public on April 18th, 1881. It was not until the following year that the cases destined to receive the larger collections of the Zoological Department were sufficiently complete to allow of these collections following, and three more years were required before all the rooms could be brought into a state fitted for public inspection. The last that was opened was the gallery devoted to British Zoology, in May, 1886.

The following description of the structure has been contributed by Mr. Waterhouse:—

"The New Natural History Museum will, from its position, always be more or less identified with the International
Exterior.

Exhibition of 1862, which occupied the whole of the site between the Horticultural Gardens and Cromwell Road. It was at one time thought that a portion, at any rate, of the Exhibition buildings could with advantage have been converted into a Museum of Natural History. Parliament, however, decided against the preservation of any part of these buildings, and they were accordingly entirely removed.

"In designing the present building, Captain Fowke's original idea of employing terra-cotta was always kept in view, though the blocks were reduced in size, so as to obviate, as far as possible, the objection to the employment of this material, arising from its liability to twist in burning. For this and other reasons the architect abandoned the idea of a Renaissance building, and fell back on the earlier Romanesque style which prevailed largely in Lombardy and the Rhineland from the tenth to the end of the twelfth century.

"In 1873, a contract was entered into by the Government with Messrs. George Baker and Sons, of Lambeth, for the erection of the building at a cost of £352,000. Other subsequent contracts have been entered into by the Treasury, especially one for the erection of the towers; which in the first instance it was decided to omit.

"On looking at the exterior of the building, one of the first points which strikes a spectator is that the site is lower than the street. This arises from the fact that the whole surface of the ground between the three roads was excavated for the Exhibition building of 1862, and it was not thought desirable, for economical considerations, to refill the space. The building is set back 100 feet from the Cromwell Road, and is approached by two inclined planes, curved on plan and supported by arches, forming carriage-ways. Between the two are broad flights of Craigleith stone steps, for the use of those approaching the building on foot. The extreme length of the front is 675 feet, and the height of the towers is 192 feet. The return fronts, east and west, beyond the end pavilions, have not yet been erected.*

* In judging the appearance of the exterior of the building, it must never be forgotten that these fronts are required to complete the design, as the externally unsightly brick galleries which run back from the main front, and are now conspicuous when the Museum is seen from either west or east, are intended to be concealed by them.
"On entering the main portal, the visitor has before him the great central apartment of the Museum (170 feet long, by 97 feet wide, and 72 feet high), which it is intended to use as an Index or Typical Museum. The double arch in the immediate foreground which spans the nave (57 feet wide), carries the staircase from the first to the second floor. Opposite the spectator, at the end of the hall, is the first flight of the staircase, 20 feet wide, which rises from the ground to the first floor. The galleries over the side recesses form the connection between the two staircases, and are also intended for exhibition space, as are also the floor of the main hall and the side recesses under the galleries. The arches under the side flights of the main staircase at the end of the hall lead into another large apartment, cruciform on plan, intended for the exhibition of specimens of British Natural History, with an extreme length of 97 by 77 feet measured into the arms of the cross.

"Branching out of the Central Hall, near its southern extremity, are two long galleries, each 278 feet 6 in. long by 50 feet wide. These galleries are repeated on the first floor, and in a modified form on the second floor. They are divided into bays by coupled piers arranged in two rows down the length of the galleries, and planned in such a manner as to allow of upright cases being placed back to back between the piers and the outer walls, so as to get the best possible light upon the objects displayed in the cases with the least amount of reflection from the glass, and leaving the central space free as a passage. Owing to the nature of the specimens exhibited in one or two of these galleries requiring for their exhibition rather table-cases than wall-cases, advantage has only been taken to a limited extent of this disposition of the plan. These terra-cotta piers, however, are constructively necessary, not only to conceal the iron supports for the floor above, but to prevent these supports being affected in case of fire. Behind these galleries on the ground floor are a series of toplighted galleries, devoted, on the east side to Geology and Palæontology, and on the west to Zoology.

"The towers on the north of the building have each a central smoke-shaft from the heating apparatus, the boilers of which are placed in the basement, immediately between the towers,
while the space surrounding the smoke-shafts is used for drawing off the vitiated air from the various galleries contiguous thereto. The front galleries are ventilated into the front towers, which form the crowning feature of the main front. These towers also contain, above the second floor, various rooms for the work of the different heads of departments, and on the topmost storey large cisterns for the purpose of always having at hand a considerable storage of water in case of fire. On the western side of the building, where it is intended that the Zoological collection shall be placed, the ornamentation of the terra-cotta (which will be found very varied both within and without the building) has been based exclusively on living organisms. On the east side, where Geology and Palæontology find a home, the terra-cotta ornamentation has been derived from extinct specimens.

"The Museum is the largest, if not, indeed, the only, modern building in which terra-cotta has been exclusively used for external façades and interior wall-surfaces, including all the varied decoration which this involves."

The space covered by the building itself, including the detached portion behind, which contains the collections of animals preserved in spirit, is nearly four acres.

The whole ground on which the Museum stands, including the gardens which surround it on the south, east and west sides, is 12 acres and 635 yards. The gardens are open to the public whenever the Museum itself is open, under certain regulations which are posted at the entrance gates.
OBJECTS OF THE MUSEUM AND GENERAL ARRANGEMENT OF ITS CONTENTS.

Natural History is an old term, used to describe the study of all the processes or laws of the Universe, and the results of the action of those processes or laws upon the materials of which it is composed, which are independent of the agency of man.*

It is thus contrasted with the history of Man and of his works, and the changes which have been wrought in the Universe by his intervention.

This distinction afforded a convenient and rational basis for the division of the numerous and multifarious objects which were collected together in the old building of the Museum at Bloomsbury. When it was decided, for the causes described in the previous chapter, to effect a separation of the collections, those that were purely the products of what are commonly called "natural" forces were removed to the new building at South Kensington, while all those which showed the effects of Man's handiwork remained at Bloomsbury. Like most others in nature, this distinction cannot be applied too rigidly. Such lines of demarcation almost always overlap. For instance, examples of modification of animal or plant structure under Man's influence will legitimately find a place in a Museum of Natural History, especially as they may afford illustrations of the mode of working of natural laws.

Processes or laws cannot, however, be satisfactorily demonstrated in a museum; therefore such branches of knowledge as deal chiefly with them, as Astronomy, Physics, Geology (in the stricter sense of the word), and the experimental sciences, as Chemistry and Physiology, though essentially belonging to the domain of Natural History, have not found a place here. It is only the results of the working of these processes or laws as shown in the modifications of the arrangement of the elementary substances of which the material of the Universe is composed,

* "Natural history—is the history of such facts or effects of nature as have no dependence on man's will."—Hobbes, 1651.
which can be fully illustrated by specimens admitting of being readily preserved and permanently exhibited in a museum. A Natural History Museum, therefore, in the sense in which the term is now usually understood, is a collection of the various objects, animate and inanimate, found upon the earth in a state of nature. It will be readily understood that as the study of such objects is one of the principal means by which the laws which have led to their formation or arrangement may be traced out, it is of the utmost importance for the progress of those departments of knowledge which the Museum is designed to cultivate, to bring together as complete an illustrative series of them as possible.

Although the validity of the old division of all natural objects into inorganic and organic or living has been the subject of some discussion, and although the separation of the latter into vegetable and animal is perhaps less absolute than was once supposed, yet for practical purposes, MINERAL, VEGETABLE, and ANIMAL still remain the three great divisions or "kingdoms" into which natural bodies are grouped, and this classification has formed the basis of the arrangement of the collections in the Museum.

I. Inorganic substances occur in nature in a gaseous, liquid, or solid form. With very few exceptions, it is only in the latter state that they can be conveniently preserved and exhibited in a museum, and it is to such that the term "mineral" is commonly limited. The collection, classification and exhibition of specimens of this kind is the office of the Mineralogical Department of the Museum, to which is devoted the large gallery on the first floor of the east wing of the building.

II. The study of the vegetable kingdom, as far as it can be illustrated by preserved specimens, is the province of the Department of Botany, which occupies the upper floor of the east wing.

III. In the same way the animal kingdom belongs to the department of Zoology, to which is assigned the whole of the western wing of the building.

It will thus be seen that a department of the Museum corresponds with each of the great divisions of natural objects; there is, however, a fourth department, which owes its separate
existence to a period of scientific culture in which the terms Zoology and Botany were limited to the study of the existing forms of animal and plant life, and the extinct or fossil forms were associated with the minerals, rather than with their living representatives. This arrangement prevailed in the British Museum until the year 1857. The fossils were then severed from this incongruous connection, and placed in a separate department for which the name of "Geology" was reserved.*

The result is that there are now two distinct zoological and botanical collections in the building, one containing the remains of all the animals and plants which have lived through successive ages of the world's history from the earliest dawn of life down to close upon the present time, and the other containing only those living at the particular period in which we dwell. Notwithstanding the objections which may be urged against this primary division of living things, it is one which prevails largely in museums, and which, owing to certain conveniences, as well as to the difficulty and expense of rearranging extensive collections and reorganising the staff in charge of them, will probably be retained for some time to come.

Besides the four above-mentioned departments, into which the collection is divided for the purposes of custody and administration, each of which is under the charge of an officer called "keeper" and a special staff of assistants, there is a fifth, at present under the immediate supervision of the Director, and arranged in the Central Hall, which is intended to be an introduction to all the others. The formation of this has only recently commenced, and owing to the difficulty of procuring the most illustrative specimens when required, and the time needed for their preparation and arrangement, some years must elapse before it can be completed.

When the last-named collection is more fully developed, the whole of the specimens contained in the Museum, whether Animal, Vegetable or Mineral, will be arranged in three distinct series, each having its definite end and purpose.

* Palæontology, or the study of ancient living beings, would have been a more appropriate designation, as Geology, the science which investigates the history of the earth, and the changes which its surface has undergone in attaining its present condition has a much wider scope.
I. An Elementary or Introductory Series, by which the study of every group should commence, in which the leading features of the structure, and, as far as may be, the development of the various parts of some of its most typical members, are demonstrated in a clear and simple manner, and the terms used in describing and defining them explained by means of illustrative examples. This has been already carried out in the Department of Mineralogy, in a series of cases placed on the north or left-hand side of the gallery containing the rest of the collection. The introductory series to the zoological and botanical collections has just been referred to as under arrangement in the Central Hall.

II. The Exhibited Systematic Series, in which the most important types of animal, plant, or mineral forms are shown, by means of carefully-selected and well-preserved specimens, arranged in a systematic manner, or one which exhibits, as far as may be, their natural relations to each other. Classification is an important feature in this series, which should be so complete and so arranged as to ensure that every visitor to the Museum can find, without recourse to assistance from the officials, every well-known and very distinct form of animal, plant or mineral, and satisfy himself about, at least, its external characters. In carrying out this ideal, great modifications must be made in practice, partly depending upon the readiness, or the reverse, with which the members of different groups lend themselves for exhibition, partly upon the exigencies of space, and partly upon special circumstances which render the exhibition of the leading forms of some groups of more interest than those of another.

While the two series above mentioned have for their object the diffusion of scientific knowledge, the next ministers mainly to its advancement, and thus between them the twofold object of a National Museum of Natural History is carried out.

III. The Reserve or Study Systematic Series contains all those exceedingly numerous specimens (in many groups, the great bulk of the collection in fact) showing the minute distinctions which are required for working out the problems of variation according to age, sex, season, and locality, for fixing the limits of geographical distribution, or determining the range in geo-
logical time: distinctions which, in most cases, can only be appreciated when the specimens exhibiting them are kept under such conditions as to admit of ready and close examination and comparison. It is to this part of the collection that zoologists and botanists resort to compare and name the animals and plants collected in expeditions sent to explore unknown lands, to work out biological problems of the highest scientific importance, and generally to advance the knowledge of the science. In fact it is these reserve collections, occupying comparatively little room, kept up at comparatively little cost, and visited by comparatively few persons, which constitute, from a scientific point of view, the most important part of the Museum, for by their means new knowledge is obtained, which, given forth to the world in the form of memoirs, books, or lectures, is ultimately diffused over a far wider area than that influenced even by the exhibited portions of the Museum. Indeed, without the means of study they afford, the order, arrangement, and power of imparting knowledge, which the exhibition galleries possess, would not be possible.

It is important to bear in mind that if the whole of such specimens as are really required for enlarging the boundaries of knowledge were displayed in the public galleries, so that each one could be distinctly seen, a museum very many times larger than the present one would not suffice to contain them; the specimens themselves would be quite inaccessible to the examination of all those capable of deriving instruction from them, and owing to the disastrous effects of exposure to light upon the greater number of preserved natural objects, would ultimately lose almost everything that now gives them value. This portion of the collection must, in fact, be treated as are the books in a library, and only used for consultation and reference by duly accredited students.*

In some parts of the Museum the reserve collections are contained in drawers beneath the cases in which the corresponding exhibited portion is placed. This applies principally to the palæontological specimens, the shells, and the minerals. The reserve birds and insects have special rooms devoted to them.

* For conditions as to admission and regulation, see p. 55.
and the extensive series of reptiles, fishes, and other animals preserved in spirit, are kept for the purposes of safety in a separate building behind the Museum. In the Botanical Department the reserve collections are kept as usual in the well-known form of an Herbarium or \textit{Hortus siccus}.

The great bulk of the specimens being arranged in these three series, there might still be supplementary collections for facilitating the study of the distribution of animals and plants, and perhaps also of minerals, in space and in time. The first, constituting a geographical series, might show by illustrative examples the leading characteristics of the fauna and flora of each great region of the earth's surface; the second, or geological series, would give examples of the fossil remains found most abundantly in each formation, arranged as far as may be in chronological order.

With regard to geological collections, although the specimens in the department so called are mainly arranged not geologically, or according to stratigraphical position, but according to their natural affinities; yet, in many cases, it has been found convenient to adopt a mixed arrangement, the specimens within each large natural group being classified according to the sequence in age of the strata in which they were found. Such an arrangement however is only applicable to the fossils of a particular region, owing to the great difficulties in accurately determining the correspondence in age of formations occurring in distant parts of the earth's surface; hence a large and varied palæontological collection, such as that of the British Museum, must be arranged in the main upon a systematic or zoological and botanical basis. A limited but instructive series, showing the most characteristic fossil remains of the various British strata, arranged in chronological sequence, is exhibited in one of the galleries of the Geological Department.
TOPOGRAPHICAL DESCRIPTION OF THE MUSEUM AND ITS CONTENTS.

In following this short account of the contents of the various sections of the building, the visitor must bear in mind that the principal front faces the south, and that therefore on entering the great hall he will be looking due north, with the east on his right, and the west on his left hand.

THE CENTRAL HALL.

Immediately confronting the visitor on entering is placed a specimen of the bony framework of one of the most colossal of animals, for which space cannot at present be found in its proper locality—the Cetacean gallery. It is the skeleton of the Cachalot, or Sperm-whale (Physeter macrocephalus), prepared from an animal cast ashore near Thurso, on the north coast of Scotland, in July, 1863, on the estate of Capt. D. Macdonald, R.E., by whom it was presented to the Museum. The Sperm-whale is the principal source of supply of the sperm oil and spermaceti of commerce. The former is obtained by boiling the fat or blubber lying beneath the skin over the whole body; the latter, in a liquid state at the ordinary temperature of the living animal, is contained in cells which fill the immense cavity on the top of the skull. It feeds chiefly on Cephalopods (squid and cuttlefish), and also fish, and is widely distributed throughout the warm and temperate regions of both Atlantic and Pacific Oceans. The skeleton is that of a full-grown animal. It measures fifty feet one inch in length, but wants three of the vertebrae from the end of the tail.

In order to render this skeleton more instructive, and to bring it into relation with the elementary specimens of osteology in the adjoining bay (No. 1., west side), the names of the principal parts have been attached to them. This will enable the anatomist to trace at a glance the extraordinary modifications in the form and relations of its component bones which the
huge skull has undergone, and will show in the clearest manner to the least instructed visitor that the so-called fin or flipper of the whale is composed of all the same parts—shoulder, elbow, wrist, and fingers—as his own arm and hand. The hind limbs are entirely absent; but two bones are seen suspended at some distance from the spinal column, which represent the pelvic or hip bones of other animals. In some species of whales there are even traces of the thigh, knee-joint, and leg attached to this, and like it deeply buried within the body of the animal.

It is intended to place cases on the floor of the hall illustrating general laws or points of interest in Natural History which do not come appropriately within the systematic collections of the departmental series. One group already in place, shows that two forms of Crows which appear quite distinct, and which, judged by their external characters, might be held to be different species, may in a state of nature unite, and produce offspring of a perfectly intermediate character. In the same case is also a series of Goldfinches, showing a complete gradation between birds of different coloration, and which have naturally been held to be different species. Both these examples may by some naturalists be considered instances, not of crossing of distinct species, but of "dimorphism," or the occurrence of a single species in nature under two different outward garbs; but from whatever point of view they are regarded, they illustrate the difficulty, continually increasing as knowledge increases, of defining and limiting the meaning of the term "species," of such constant use in biology.

Another case is in preparation to show the great variation to which a species may become subject under the influence of domestication, as illustrated by choice examples of the best marked breeds of Pigeons.

The bays or alcoves round the hall, five on each side, are devoted to the Introductory or Elementary Morphological Collection, designed to teach the most important points in the structure of the principal types of animal and plant life, and the terms used in describing them, all which should be known before the systematic portion of the collection can be studied with advantage. This has been called the "Index Museum," as it was thought at one time that it would form a sort of
epitome or index of the main collections in the galleries; but the name does not exactly express what it has developed into. It is really more like the general introduction, which almost always precedes the systematic portion of treatises on any branch of natural history. As mentioned before (p. 17), this collection is at present far from complete; in fact, only in its infancy; and as nothing exactly like it has been exhibited in any public museum before, it may, as its formation goes on, be subject to much modification and improvement; but it is hoped that it may ultimately serve as a guide for the formation of educational biological museums elsewhere. The space being strictly limited, the number of illustrative specimens is necessarily restricted, probably to the advantage of the student, at all events in the earlier part of his career. In examining this collection the visitor should follow each case in the usual order of reading a book, from left to right, and should carefully study all the printed explanatory labels, to which the specimens are intended to serve as illustrations.

The bays on the west side (left-hand on entering the hall) are devoted to the Vertebrated Animals, or those possessing a "backbone." In Nos. I. and II. are shown the characters of the Mammalian modifications of this type. The wall-cases of No. I. are already nearly filled with specimens showing the bony framework (internal skeleton) of Mammals.

In the first case (south side of the recess) will be seen a complete skeleton of a good example of the class—a large monkey, with all the bones separated, laid out on a tablet, and with their names affixed to them. Below it is a skeleton of the same animal articulated, or with the bones in their natural relation to each other, and also named. By examining these two specimens, a fair idea may be obtained of the general framework of the body of animals of this class. In other parts of the case are placed examples of modifications of the skeleton to suit different conditions of life.

1. Man, showing a skeleton adopted for the upright position.
2. A Bat, or flying mammal, in which the fore-limbs are converted into wings by the great elongation of the fingers, which support a web of skin stretched between them.
3. A Sloth, in which the ends of all the limbs are reduced to
mere hooks, by which the creature hangs back-downwards from the boughs of the trees, among which it passes its entire existence.

4. The Baboon serves as an example of an animal walking on all four limbs in the “plantigrade” position, i.e., with the whole of the palms of the hands and soles of the feet applied to the ground.

5. A small species of Antelope shows the characteristic form of a running animal, in which the limbs perform no office but that of supporting the body on the ground. It stands on the tips of the toes of its elongated slender feet.

6. A Porpoise, adapted solely for swimming in the water. The fore limbs are converted into flattened paddles, and the hind limbs are entirely absent, their function being performed by the tail. The rudimentary pelvic bones are preserved.

The rest of the case is occupied by details of the skull in some of its principal modifications. At the top are diagrams showing the structure of bone and cartilage as shown by the microscope.

In the wall-case on the opposite (north) side of the bay the outline of the osteology of mammals is continued by illustrations of the structure of the limbs. At the top of the case is a diagram showing the correspondence of the hand and the foot in its complete typical form, with the names applied by anatomists to the different bones. The series of specimens below show the principal deviations which actually occur from the typical condition, which, as will be seen, is very nearly preserved in the human hand. One interesting series shows some of the stages of modification for special purpose (specialization) by which a typical five-fingered hand becomes converted into that of the single-fingered Horse, and another series ends with the hand of the ruminants, with only two fingers remaining, sometimes, but erroneously called a “cloven hoof.” Similar changes are shown in the toes of the hinder extremity, illustrating the same common plan running through infinite modifications in detail, enabling the organ to perform such a variety of purposes, and to exhibit such diversity of outward appearance. The existence of this common plan is now generally thought to be due to inheritance from a common ancestor.

In the lower part of the case are examples of all the different kinds of articulations or joints by which the various bones of the body are connected together.
The central case of the bay contains a collection illustrating the principal characters of the teeth in the Mammalia. Its inspection should commence at the north-east corner, where the visitor will find himself, after completing the survey of the osteological specimens in the wall-cases. In the first division specimens are placed showing the general characters of teeth, their form, the different tissues of which they are composed, the two great types of dentition in mammals, *homodont* and *heterodont*, the nomenclature and homologies of the different teeth, and their development and succession. The principal modifications of teeth according to their function are next shown, by examples of forms adapted for fish-eating, flesh-eating, insect-eating, grass-eating, &c. The remainder of the case is taken up by select examples of the dentition of all the different families of mammals arranged in systematic order, prepared so as to display not only the shape of the crowns, but also the number and character of the roots by which they are implanted.

Bay No. II. contains, in its first wall-case (the only one yet occupied), illustrations of the outer covering or integument and its modifications in the class of Mammals, divided into the following sections:

1. Expansion of skin to aid in locomotion, as the webs between the fingers of swimming and flying animals, the parachutes of flying animals.

2. The development of true bony plates in the skin, found among mammals only in the Armadillos and their allies. The cast of a section of the tail of a great extinct species (*Glyptodon*) shows well a bony external as well as internal skeleton.

3. The outer covering modified into true scales, much resembling in structure the nails of the human hand. This occurs in only one family of mammals, the Pangolins or *Manidae*.

4. Hair in various forms, including bristles and spines. A stuffed specimen of a Porcupine at the bottom of the case affords a good illustration of a spiny covering. The two kinds of hair composing the external clothing of most mammals, the long, stiffer outer hair, and the short, soft under fur, are shown by various examples.

5. The special epidermal appendages found in nearly all
mammals on the ends of the fingers and toes, called according to the various forms they assume, nails, claws or hoofs.

6. The nasal horns of the Rhinoceros, shown by sections to consist of a solid mass of hair-like epidermic fibres.

7. The horns of Oxen, Goats and Antelopes, consisting of a hollow conical sheath of horn, covering a permanent projection of the frontal bone (the horn-core).

8. The antlers of Deer, solid, bony, generally branched, projections, covered during growth with soft vascular hairy skin, and shed and renewed annually.

The other systems of organs of the class will occupy the remainder of this bay.

Bay No. III. is devoted to the class of Birds. In the first wall-case the principal facts in the osteology of the class are shown. Sections of bones exhibit the large air cavities within; a complete skeleton of an Eagle, with the bones separated and named, and mounted skeletons of the Ostrich, Penguin, Pelican, Vulture, Fowl, &c., show the chief modifications of the skeleton. The Apteryx shows the smallest, and the Frigate bird the largest bones of the wing, the correspondence of which can be readily traced by means of the labels attached to them. The under surface of the skulls of various birds are shown with the different bones coloured to indicate their limits and relations, followed by a series of the different types of sternum or breast-bone.

The table-case in the middle of the bay contains illustrations of the external characters, the beak, the feathers and the tail, as well as of the fore and hind limbs, or wings and feet.

Bays IV. and V. completing the west side of the hall, will, in a similar manner, show the most important points in the structure of reptiles and fishes. In the latter has already been placed a very fine skeleton of the Great Blue Shark (*Carcharodon rondeletii*) from New Zealand, with the names of all the parts affixed to them.

Of the bays on the east side of the hall, No. VI. is for the illustrations of the articulated classes, Crustacea, Arachnida, Myriopoda and Insecta, as well as of the Annulosa and Vermes. No. VII. for the Mollusca, Echinodermata, Coelenterata, Porifera and Protozoa; and the remaining three, VIII., IX., and X., for the morphology of the vegetable kingdom: the first containing the
Cryptogams, the next the Gymnosperms and the Monocotyledons, and the last the Dicotyledons. By this arrangement the lowest or simplest forms of animal or plant life, those on the border land, as it were, of the two kingdoms, will be brought into contact, and at the two ends of the series, in Bays I. and X., will be found the groups which show in the highest degree the special attributes of the division to which they belong.

The Introductory Collection of Minerals will be found in the gallery devoted to that department of the collection (see p. 43).

**Gallery of British Zoology.**

At the north end of the Central Hall, with entrances on either side of the great staircase, is a large room containing a collection of animals of all classes, which are, or have been in recent times, found in the British Isles, either as permanent residents, or as regular migrants or occasional visitors. The animal inhabitants of any country or district are collectively termed its "fauna." Our country in this respect belongs to the great zoographical region called Palæarctic, embracing all Europe, the north of Africa, and the western and northern portions of Asia. As in the case of all islands, the species belonging to groups whose powers of locomotion are limited to the land or fresh water, are not numerous compared with those inhabiting large continental tracks. Their numbers can only increase under very exceptional circumstances, but, on the contrary, have a tendency to diminish, as the growth of human population and increase of the area of cultivated land gradually circumscribe their native haunts. In this way, the Brown Bear, the Wolf, the Beaver and the Wild Boar have all disappeared from Britain within the historic period, and others, as the Badger, Marten and Wild-cat, with difficulty maintain a somewhat precarious existence. These have all been originally derived from the mainland of Europe, probably before the formation of the channel which now makes our country an island. The wider and older channel which separates Ireland from Great Britain has proved a greater barrier to the emigration of animal life than that between the latter and the Continent, many species (as the Polecat, Wild-cat, Mole, Squirrel, Dormouse, Harvest-mouse,
Water and Land Vole, Common Hare, Roe deer, as well as Snakes and Toads) never having crossed it, unless by aid of human agency.

On the other hand, those species that have the power of travelling through the air or traversing the ocean are far less fixed in their habitat, and thus the list of so-called “British birds” receives accessions from time to time from stragglers which find their way from the European continent or even across the Atlantic, and doubts as to the authenticity of some of the recorded occurrences make the list rather a vague and uncertain one. The constitution of the marine fauna in the same way is continually liable to undergo fluctuations.

Slight but permanent variations from the continental type can be recognised in a few of our indigenous species, but the only vertebrated animals undoubtedly peculiar to the British Isles are the common Red Grouse (*Lagopus scoticus*), and several species of fresh-water fishes (fifteen are enumerated by Dr. Günther), mostly belonging to the genus *Salmo*. Some of these have an extremely local distribution, being only found in some small groups of mountain lakes. Many species, or at all events, well-marked varieties of insects, and a few land and fresh-water molluscs, have at present been only found within the limits of our islands.

**Staircase.**

On the first landing of the great staircase, facing the centre of the hall, is placed the seated marble statue of CHARLES DARWIN (b. 1809, d. 1882), to whose labours the study of natural history owes so vast an impulse. The statue was executed by Mr. J. E. Boehm, R.A., as part of the “Darwin Memorial” raised by public subscription. It was unveiled and placed under the care of the Trustees of the Museum on the 9th of June, 1885, when an address was delivered on behalf of the Memorial Committee, by the Chairman, Professor Huxley, P.R.S., to which His Royal Highness the Prince of Wales, as representing the Trustees, replied.

Above the first landing the staircase divides into two flights, each leading to one of the corridors which flank the west and
east sides of the hall, and by which access is gained to the galleries of the first floor of the building. At the southern end of these corridors a staircase from each, raised on an arch which spans the hall, join to form a central flight leading to the second or uppermost floor. On the landing at the top of this flight is placed a marble statue by Chantrey of Sir Joseph Banks (b. 1743, d. 1820), the munificent patron of science and scientific men, who for forty-one years presided over the Royal Society, and was an active Trustee of the Museum. His splendid botanical collections are preserved in the adjoining gallery, but his unrivalled library of works on natural history, also bequeathed to the Museum, remains in the old building at Bloomsbury, in the entrance hall of which the statue, erected by public subscription in 1826, stood, until it was removed to its present situation by direction of the Trustees in the year 1886.

The west corridor contains a portion of the series of British birds with their nests (see the following page), for which there is not room in the Bird Gallery on the ground floor.

In the east corridor is placed at present the collection of Humming-birds (Trochilidae) arranged and mounted by the late Mr. John Gould, and purchased by the Museum after his death in 1881. The resplendent colours and infinite varieties of form presented by these fairy-like objects must always excite feelings of admiration and wonder in all who gaze upon them. A special guide-book, pointing out the most interesting features of this collection, with a general account of the geographical distribution and mode of life of the humming-birds, has been published by the Trustees.*

WEST WING.

The whole of the west wing of the building is devoted to the collections of recent Zoology.

(A) Ground Floor.

The ground floor is entered from the west side (left hand) of the Central Hall, near the main entrance of the building. The

long gallery extending the entire length of the front of the wing is assigned to the exhibited collection of birds, the study series of the same group being kept in cabinets in a room behind.

The wall-cases contain mounted specimens of all the principal species arranged in systematic order, beginning with the Vultures, on the left hand on entering, and ending with the Penguins on the right. The arrangement adopted is that of the Catalogue, now in course of publication, in a series of octavo volumes.

From the multitude of specimens which are exhibited in this gallery, and which form but a small proportion of the different kinds of birds known to inhabit the globe, only a few of the most striking can be mentioned here. The various types of the birds of prey are very fully represented: from the Condor or Great Vulture of the Andes, the large Sea-eagle of Behring Straits, and the Great Eagle Owl of Europe, all of which are placed in separate cases, to the Dwarf Falcon in case 13, which is not much larger than a sparrow, and preys upon insects. Of the large group of perching birds, attention is drawn to the case of birds of Paradise opposite to wall-cases 17 and 20. At the end of the same side of the gallery are placed skeletons of the Dodo and Solitaire, gigantic pigeons with wings too small for flight, once inhabitants of the islands of Mauritius and Rodriguez, but now extinct. The cases on the right-hand side of the gallery are occupied by birds allied to the common Fowl, and by the wading and swimming birds; among them a fine series of Pheasants and other game birds; the Great Bustard, once an inhabitant of our island; a pair of Flamingoes with their nest; the Great Auk from the Arctic Seas, now extinct; and finally the large Emperor Penguin from the Antarctic Ocean, the only known specimens of which were obtained on the British antarctic expedition of 1839–43.

In the middle of the room and in the spaces between the wall-cases are placed various isolated groups of particular interest, among which the visitor will doubtless be attracted by those showing the nesting habits of our best-known British birds. The great value of these groups consists in their absolute truthfulness. The surroundings are not selected by chance or imagination, but in every case are carefully-executed reproductions of those
that were present round the individual nest. When it has been possible, the actual rocks, trees or grass, have been preserved, and where these were of a perishable nature they were accurately modelled from nature. Far more care has also been taken in preserving the natural form and characteristic attitude of the birds than was formerly the case in museums, as a large number of the old specimens in the wall-cases unhappily testify. This beautiful and instructive series is still in process of formation. Owing to want of space in this gallery, the nests of the Perching or Passerine birds are placed for the present in the west corridor of the Central Hall.

In the "Pavilion," or room at the further end of the gallery, are placed the specimens of the peculiar division of birds, called Ratitae, from the flat or raft-like character of the breast-bone, and which, owing to the rudimentary character of their wings have not the power of raising themselves off the ground in flight. They include the largest existing birds, the Ostriches, Emus and Cassowaries, as well as the small Kiwi or Apteryx of New Zealand.

Parallel with the bird gallery to the north side (right on entering), and approached by several passages, is a long narrow gallery containing the collection of corals and of sponges and allied forms. Coral Gallery. Commencing at the eastern end, some of the lowest forms of animal life are exhibited in the wall-case and table-cases; they belong to a group called Foraminifera, and, for the greater part, are so minute, that they can be studied with the microscope only; their structure is therefore illustrated by means of models and figures. The next divisions of the gallery are occupied by the sponges; most conspicuous among them is a series showing the variations of the common bath-sponge (cases 1 and 2), the beautiful siliceous Euplectella or Venus' flower basket, and the Japanese Hyalonema or glass rope sponge (case 3), and the gigantic Rhaphiophora or Neptune's goblet, of which several specimens are placed on separate stands.

Nearly the whole of the remainder of the gallery is given up to the Corals, showing the immense variety of form and colour of these animals, some presenting a marvellous resemblance to vegetable growths. The part exhibited is merely the dried, hard, horny or calcareous basis or supporting skeleton either of
isolated individuals, or of colonies of creatures allied to the well-known sea-anemones of our coasts. Opposite to cases 8 and 10, which contain the Madrepore Corals, is placed a large fragment of a reef, entirely formed by a small kind of Madrepore. These reefs when raised above the surface of the water constitute the base of thousands of islands in the Indo-Pacific Ocean. Of the host of other forms, only the precious coral (Corallium), usually of a bright red colour, found in the Mediterranean and so largely used for ornamental purposes, and the crimson Organ-pipe Coral (Tubipora) in case 13, can be mentioned here.

The wall-case at the western end of the gallery contains the Polyzoa, a group of small animals which, like corals, are supported by a calcareous or horny plant-like growth, but in their internal structure are more nearly related to the Mollusca, a class exhibited in the adjoining gallery.

Approached through the Coral Gallery, and running backwards at right angles with it, are a number of galleries containing other portions of the zoological collections.

In the corridor which leads from the Bird Gallery into the Fish Gallery a large table-case is placed, containing a selection of the most important forms of Batrachians, which are divided into such as possess a tail—Salamanders and Newts, and into those without tails—Frogs and Toads. These animals live during some period of their existence in the water, and breathe by gills, and are therefore very closely allied to fishes.

Fish Gallery. I. The Fish Gallery, which is nearest to the Central Hall, contains the exhibited portion of the collection of Fishes, the greater number of which, preserved in spirit, are placed for safety in a detached building behind the Museum, where they are available for study under suitable regulations. The gallery contains stuffed examples and skeletons of all the most remarkable members of the class, the peculiarities of which will be pointed out in a special guide-book which will shortly be published.

The wall-cases on the west side of the room (right on entering) and at its end contain the fishes with completely osseous skeletons, a division to which belong by far the greater part of the species now inhabiting the waters of the globe. Large and remarkable examples are placed in separate cases opposite to
the wall-cases; and as the colours of fishes are very fugitive, and disappear more or less completely after death, some of the stuffed examples have been painted from life, to show the extraordinary brilliancy of many of the tropical kinds. The fishes allied to the Perch (case 1), Gurnard (case 8), Mackerel (case 10), Sword-fish (case 13), Wrasse (case 14), Codfish and Plaice (case 16), Catfish (case 17), Salmon (case 19), Pike (case 20), Carp and Herring (case 21), Eel (case 23), are represented by numerous examples, the last of which is that, at least in external form, most remarkable fish, the Sunfish or Orthagoriscus.

The eastern or left side of the room is devoted to the exhibition of a very different division of fishes, which was much more numerously represented in ancient times than at present. The majority have a cartilaginous skeleton. To this division belong the Gar-pike of North America (case 28), the Mud-fishes (Dipnoi) of South America, Africa and Australia (case 28), the Sturgeons (case 29), and finally the Sharks and Rays, including the singular Hammer-headed Shark, and the Saw-fish (Pristis) which has a long projecting flattened snout, with a row of teeth arranged something like those of a saw on each side. Another very small division of fishes comprises the Lampreys, of which a few specimens are shown in case 44.

The largest specimen of the class, placed near the centre of the room, is a full-grown example of the Great Basking Shark (Selache maxima) which was captured on the 2nd of March, 1875, near Shanklin, in the Isle of Wight. Its length is twenty-eight feet, but as the minute size of the teeth indicate, it is a comparatively harmless animal.

II. A small gallery is devoted to the group of Articulata or Invertebrated animals with jointed limbs, as Insects, Spiders, Myriopods, and Crustacea. In the wall-cases are many curious examples of nests, and of specimens illustrating the ravages of destructive insects, and also some of their economic products. Selected examples of the different groups of insects are exhibited in systematic order in the table-cases, so as to give the visitor who studies them a good general idea of all the most interesting forms and of their classification. Unfortunately, it is impossible to exhibit many of the most beautiful and rare species, owing to the deteriorating effects of continued exposure to light upon
their colours. The main collection of insects is, on this account, and because of the immense space it would otherwise occupy, kept in cabinets in the "insect-room" on the basement floor, to which students can have access under the regulations which will be found at the end of this guide.

III. A large gallery containing the collection of stuffed specimens and skeletons of Reptiles, including Crocodiles, Lizards, Snakes and Tortoises. As in the case with the fishes, a large number of the animals of this class are necessarily preserved in spirit, and therefore not suitable subjects for exhibition. The gallery contains examples of all the forms of general interest, for an account of which the visitor is referred to the special guide.*

The fine and unique series of Gigantic Land Tortoises which are either extinct or doomed to speedy extermination; the interesting skeleton of the Leathery Turtle (Sphargis) in which the carapace is separated from the true skeleton; the large stuffed examples of the Fish-eating Gharial and of the dangerous Crocodiles of Africa, India and Australia; the Snake-eating Snake (Ophiophagus), the largest of poisonous snakes; and the great stuffed Anaconda (Boa murina) at the end of the room—are the objects which will most attract the attention of the visitors to this gallery.

IV. A small gallery is called Star-fish Gallery from being specially devoted to the Star-fishes and their allies—the Echinodermata; these are arranged systematically in table-cases 1–6, and in case 7 there are specimens illustrating the anatomy of the skeleton, and models and figures descriptive of the remarkable changes undergone by these animals in the course of their development. As magnificent examples the visitor should not fail to notice in 1 D Pycnopodia helianthoides, and in 2 B and C the fine series of Linechia, and in 2 D–F and 3 A the extensive collection of Oreaster; in 3 E are two remarkable specimens of Astropecten; in 4 C an almost complete example of the brittlestar (Ophiomastix annulosa) should be noticed, and on the tops of cases 5 and 6 are good examples of Diadema and Echinus. The most beautiful and remarkable specimens in the gallery are the stalked Crinoids, which were collected by the "Challenger," or dredged when seeking for a telegraph wire

* 'Guide to the Gallery of Reptiles.' Price twopence.
in the Caribbean Seas. These deep-sea forms, so abundant in earlier periods of the world's history, are exhibited on tables in the corners of the gallery, by case 7.

The wall-cases contain types of the very various and different groups which are put together as Worms or Vermes. Case 1 contains the Tape-worms or Cestoda, and the Flukes or Trematoda, the life history of a type of each being illustrated by specimens, figures, and models; in case 2 the Round-worms are illustrated by models of Trichina, and the anatomical structure of various other forms is shown by the aid of diagrams. Case 3 contains the free-living Terrestrial and Marine Worms, the Leeches, and Gephyreans.

V. A large gallery devoted to the extensive division of Mollusca, the exhibition of which is however mainly restricted to their shells. In some cases the form of the animal itself is shown either by specimens in spirit or by means of models.

The first table-case on the left as the gallery is entered contains the Argonauts, the beautiful pearly Nautilus, the rest of the Cephalopods (Octopus, Squids, &c.), the fragile glassy Pteropods, and the Cones, one of the most beautiful groups of the Gastropods, a division which includes Snails, Whelks, Slugs and all those Molluscs which crawl upon the under surface of their body. They are contained in cases 1–17. The Bivalves or those Molluscs which, like the Cockle and Oyster, are protected by a shell formed by two pieces or valves, are arranged in cases 17–26. The most generally known of this division are the Venus-shells (case 17); the Cockles (case 19); the Giant Clam, sometimes weighing as much as 500 lbs. each (case 20); the Piddocks and Teredos, borers in wood and stone (case 19); the Razor-shells (case 20); the Pinnas (case 24); Scallops and Thorny Oysters (case 25); and the True Oysters (case 25).

A fine series of very large shells and some interesting Cephalopods in spirit occupy four upright cases at the ends of the room; and near the entrance to the gallery are placed some small table-cases, containing series of the eggs of Mollusca and of their opercula or lids by means of which the opening or mouth of the shell is closed in some forms; also specimens illustrating
the formation of pearls, and other special points of interest connected with the group.

Special guide-books to all these galleries are in preparation.

**GALLERY OF CETACEA.**

Approached by a staircase, leading from the last (or western-most) of the passages which connect the bird gallery with the coral gallery, is a room in the basement, in which the specimens of whale-like animals, for which, on account of their large size, no other place could be found in the portion of the Museum galleries already completed, are placed. The room has, unfortunately, the disadvantage of being not well lighted, and of being intersected by massive columns, which interfere with the complete view of any of the larger skeletons; nevertheless the specimens will be safely preserved in it, until the erection of the west front will afford them better accommodation, and visitors can, in the meantime with very little difficulty study most of the important peculiarities of these gigantic and very interesting members of the Animal Kingdom.

As it is almost impracticable to preserve the skins of the larger species of whales, owing to the quantity of oil with which they are saturated, the exhibition of the characters of these animals is chiefly limited to their skeletons, assisted by drawings of their external forms. The general appearance of many of the smaller kinds is, however, shown by stuffed specimens and coloured casts. A general account of the structure and classification of the Cetacea, with special reference to those exhibited in this gallery, will be found at the end of the Guide to the Galleries of Mammalia.*

On the left side of the door, on entering, near the window, is a case containing a stuffed specimen, skeleton, and several skulls of the very curious fresh-water Dolphin of the rivers of India (*Platanista gangetica*), and in the next case the peculiar Dolphin of the river Amazon (*Inia geoffrensis*). Among the specimens on the same side of the room, one of the most interesting, on account of its remarkable dentition, is the Narwhal or Sea-

---

Unicorn. It has only two teeth, which lie horizontally in the upper jaw. In the female both remain permanently concealed within the bone of the jaw, so that this sex is practically toothless, but in the male, while the right tooth remains similarly concealed and abortive (as shown in the specimen, by removal of part of the bone which covered it), the left is immensely developed, attaining a length equal to that of half the entire animal, projecting horizontally from the head in the form of a long, straight, tapering and pointed tusk, spirally grooved on the surface. In some very rare cases both teeth are fully developed, as in the fine skull exhibited near the skeletons.

Most of the largest Cetacea belong to the group called "Whalebone Whales," in which a series of horny plates called "baleen," or more familiarily "whalebone," grow from the palate in place of teeth, and serve to strain the water taken into the mouth from the small marine animals on which the whales subsist. A fine representative of this group is the very perfect skeleton of the Common Rorqual or Fin-whale (Balaenoptera musculus) near the further end of the middle of the room. It is sixty-eight feet long, and was captured in 1882 in the Moray Firth, Scotland. The flukes of the tail and dorsal fin are preserved with the skeleton and suspended in their natural position, and the small pelvic bones and a rudimentary nodule, representing the femur or thigh bone, the only trace of the hind leg of this gigantic animal, are also preserved. Beyond this skeleton is a skull of the Greenland Right-Whale (Balaena mysticetus) which yields most of the "whalebone" of commerce, and also a small wooden model of the animal, of the scale of one inch to the foot.

First Floor.

The upper floors of the wings of the Museum consist only of single galleries extending along the whole front of the building; the galleries which run backwards on the ground floor containing only a single story.

The MAMMALIAN GALLERY is entered from the western corridor of the Central Hall. It contains the series of stuffed specimens of animals of this class, with the exception of the Cetacea and the Sirenia. Skeletons of the most important types
are incorporated with this series. The collection of antlers of the family of Deer are ranged along the top of the cases.

The contents of this gallery and the next are described in considerable detail in a special guide, and therefore a very short notice here will suffice.

The series commences on the left with the most highly organised forms, viz., the apes and monkeys, of which the fine series of Gorillas, Chimpanzees and Orang-Outangs deserves special attention. Among the Carnivora which occupy the cases next in order will be noticed the series of Tigers (cases 13 and 14), including the small and long-haired Persian race, and the large short-haired form of the jungles of Bengal. Typical forms of the Bats (such as the Flying Fox), of the small Insect-feeders and Gnawing Animals, and of the Edentata (Sloths, Anteaters and Armadilloes) follow. The remainder of the cases of this side of gallery, of the pavilion, and nearly the whole of the right side are devoted to the Ungulata or Hoofed Animals; very complete series of the wild Sheep, Goats and wild Cattle, of the Musk-ox, inhabitant of the Arctic regions, of the large African Antelopes (chiefly obtained by Mr. F. C. Selous), and of the Elk and Reindeer of both hemispheres are exhibited. Towards the end of the series, in cases 95–98, the Pouched Mammalia or Marsupialia (Kangaroos, Wombats, Tasmanian Wolf, Opossums, &c.), find their place; they carry their young in a pouch, until able to shift for themselves, in this respect reminding us of the nest-building birds. Finally the Monotremes of Australia, the Duck-billed Platypus, and the Echidna, at the bottom of case 98, differ still more from the ordinary members of this class. inasmuch as they do not bring forth their young alive, but lay eggs.

Second Floor.

The Osteological Gallery is devoted to the skeletons and skulls of Mammalia, the arrangement of which corresponds, as far as practicable, with that of the stuffed specimens. The series commences (on the left hand on entering) by a male and female human skeleton, followed by a selection of skulls, showing the different modifications of the cranial and facial bones in the
various races of Mankind. The next wall-case contains several skeletons of man-like Apes, the Orang-Outang, Gorilla and Chimpanzee, with the principal forms of the other Monkeys and Lemurs. In cases 4–8 numerous representatives of the Carnivorous and Rodent Mammalia are shown, the remainder of the cases of this side of the gallery being devoted to the exhibition of skulls of the larger Ungulata, viz., the Elephants, Rhinoceroses and Horses. Of the first many skulls are exhibited, some in section showing the extraordinary modification of the skull in adaptation to the support of the heavy tusks and powerful trunk. The series of elephants is continued in the pavilion at the end of the gallery, where skulls and skeletons of the African and Indian elephants are exhibited, among them a skeleton of a very large tuskless elephant or Mooknah.

In the pavilion are also placed skeletons of the Sirenia or Sea-Cows, aquatic animals more nearly allied to the Ungulates than to the Whales with which they were associated in former times. Stuffed examples of these animals have also been placed here for want of space in the Mammalian Gallery.

The majority of the cases on the right hand of the gallery are occupied by the Ruminant Ungulata, such as the Camels, Oxen, Antelopes, Sheep, Goats and Deer; cases 23 and 24 containing the Edentata (Sloths, Anteaters, Armadilloes), the Marsupials or Pouched Mammalia, and finally the Monotremes of Australia (Ornithorhynchus and Echidna) which in their skeleton as well as other structures differ widely from the ordinary members of the class.

Along the centre of the gallery is ranged a very complete series of skeletons of the wild cattle of the old and new world, and of the various species of Rhinoceros and Hippopotamus.

A collection of horns of Oxen, Buffaloes, Antelopes and Sheep is placed on the top of the cases of the gallery and on the wall of the saloon.
The ground floor of this wing consists, as on the other side of
the building, of a gallery running east and west the whole length
of the wing in front, of a smaller parallel gallery behind it, and
leading from the latter, a series of galleries running north and
south. The whole of this floor is occupied by the collection of
the remains of animals and plants which flourished in geo-
logical periods anterior to that in which we are now living.
Some of these belong to species still existing upon the earth,
but the great majority are extinct. They are arranged mainly
upon zoological principles, that is, the forms which are supposed
to have natural affinities are placed together, but within some of
the great divisions thus mapped out, especially of the Inverte-
brata and plants, it has been found convenient to adopt a
stratigraphical or even geographical grouping, the fossils of
different geological formations being kept apart, and those of
the British Isles separated from those of foreign localities.

As this portion of the Museum is fully described in the
Illustrated Guide* it will only be necessary to give a brief
account of it here.

The large front gallery first entered from the hall is entirely
devoted to the remains of Mammalia. Along the centre are
placed a number of large and striking objects, of too great a size
to be contained in the wall-cases. The first is a nearly complete
skeleton of the American Mastodon, an animal closely allied to
the elephant, from which it is chiefly distinguished by the
characters of its molar teeth. Beyond this is the skull of an
Elephant (*Elephas ganesa*), remarkable for the immense length
of its tusks, from the Siwalik Hills of India, and another of the
Mammoth (*Elephas primigenius*) with huge curved tusks, in a
perfect state of preservation, found in the brick earth at Ilford

* 'Guide to the Exhibition Galleries of the Department of Geology and
Palæontology,' 1886. Price fourpence.
in Essex. Then follow skeletons of the great extinct Irish Deer (*Megaceros giganteus*), male and female, the former distinguished by its magnificent palmated antlers, resembling those of a fallow deer on a large scale.

Beyond these is a skeleton of a very rare and remarkable animal, the Northern Manatee or Sea Cow (*Bhytina gigas*), the last known resort of which was Behring's Island in the North Pacific, where it was completely exterminated towards the close of the last century. In the same case is placed the skeleton of a smaller allied form, the Halitherium, from the Miocene of South Germany. These, with their existing representatives, the Manatee and Dugong (see Osteological Gallery, West Wing, Second Floor, p. 39), belong to the order *Sirenia*, aquatic mammals of fish-like form, presenting considerable external resemblance to *Cetacea* (the Whales and Dolphins), although differing from them in many essential points of structure and habit.

The wall-cases on the south side (right on entering) contain remains of Man found under such circumstances as may justify the appellation of "fossil," in caves or pleistocene deposits, associated with the bones of animals either completely or locally extinct. Then follow in systematic order the bones and teeth of the other Primates, the Carnivora, Ungulata and *Sirenia*.

The greater part of the north side of the gallery is devoted to the exhibition of a magnificent collection of the remains of Proboscidia (Dinotheria, Mastodons and elephants), including the fine series from the sub-Himalayan Mountains collected by Cautley and Falconer.

In the pavilion, or expanded portion of the end of the gallery, are skeletons and bones of the animals of the order Edentata, mostly from South America, including some fine specimens of the great Ground Sloths, the largest of which is the Megatherium, and the Glyptodon, a huge extinct Armadillo, enclosed in a solid barrel-like bony case. As these animals far surpassed in size their diminutive existing representatives, so the gigantic Australian Marsupials of the corresponding period (pleistocene, or latest tertiary), the Diprotodon and Nototherium, remains of which will be found in this room, greatly exceeded any of the species now existing on that continent. On the other hand, all
the mammals of the earliest geological periods of which remains are known, are of diminutive size, as seen in the very interesting series, mostly from the Purbeck (upper oolite) beds of Dorset, and Stonesfield (great oolite) of Oxfordshire, exhibited in one of the table-cases on the north side of the room.

The south side of this room (right on entering) is chiefly devoted to the remains of extinct birds, including the famous Lizard-tailed Bird (*Archaeopteryx*) of the Solenhofen beds of Bavaria, the oldest known member of the class, presenting many reptilian characters, but with well-developed feathers in the wings and tail, the impressions of which are beautifully preserved in the specimen. A series of skeletons of the Moa or Dinornis of New Zealand, a bird in which no trace of a wing has been discovered, show the diversity of size of different members of the group, some far exceeding any existing ostrich in size, and others scarcely larger than a good-sized turkey. Some of these remains are so recent as still to be covered with dried skin, and even feathers. Several eggs are also shown, but large as these are, they are greatly exceeded in size by those of the *Æpyornis* from Madagascar, in the south-east corner of the room.

The long gallery north of the mammalian saloon contains a fine assemblage of Reptilian remains. The south side is devoted to the great sea-lizards (*Plesiosauria* and *Ichthyosauria*), including the collection described and figured in Mr. Hawkins's Book of the Great Sea-Dragons. Ranged in the cases on the north side are remains of the gigantic *Dinosauria*, which far exceeded in size any other land animals. At the eastern end of the gallery are the *Pterosauria*, or Flying Reptiles.

Of the galleries leading backwards from this, the one nearest the centre of the building, is devoted to the collection of fossil Fishes, an account of which has been published in a special guide.* The next contains the Cephalopods, a group of animals abounding in extinct forms, of which the Belemnites and Ammonites are the best known. The form and structure of their nearest living representatives, the various species of Cuttlefishes, Squids, Argonauts and Nautilus are illustrated by models

---

* 'Guide to the Collection of Fossil Fishes in the Department of Geology and Paleontology,' 1885. Price threepence.
and drawings placed near the entrance of the gallery. The third gallery contains the remaining Molluscs, Echinoderms, Annelids and Crustacea; the fourth the Corals, Sponges, Protozoa and fossil Plants. In these last two galleries the British specimens are placed in the table-cases, and those of foreign origin in the cases round the walls.

The fifth gallery is set apart for the reception of certain special collections of historical interest, which, from the circumstances under which they were formed, or under which they came into possession of the Museum, or from their containing a large number of types described and figured in standard monographs, it has not been thought desirable to break up and disperse among the general collection. The principal of these are, the original collection formed by William Smith, the pioneer of geology in this country, the Searles Wood Collection of Crag Mollusca, the Edwards Collection of Eocene Mollusca, the Davidson Collection of Brachiopoda, the types of Sowerby's 'Mineral Conchology,' and lastly, but not least in interest, the specimens which, belonging to the collection of Sir Hans Sloane, form the nucleus of the whole Museum.

In the wall-cases on the west side of this gallery is exhibited a stratigraphical collection, intended to show the most characteristic organic remains of the various geological formations of the British Isles, arranged in the order of their sequence in time, commencing near the entrance door with the most recent and gradually passing down to the most ancient fossil-bearing strata.

**First Floor.**

The one large gallery on this floor, entered from the south end of the east corridor of the hall, contains the extensive and well-arranged collection of Minerals.

The value of this collection to the intelligent visitor is greatly enhanced by the publication of an 'Introduction to the Study of Minerals,' as a part of the general guide to the gallery, and by the arrangement of a series of specimens in four window-cases on the left-hand side of the gallery on entering, illustrative of historical collections.

of the statements in this Introduction. It is particularly recommended that this series should be carefully studied before the attention is directed to the large collection of minerals arranged in systematic order which fill the table-cases of the body of the room.

In the pavilion at the end of the gallery will be found certain mineral specimens too large for exhibition in the table-cases of the gallery, and a case containing a series of specimens arranged by Mr. Ruskin to illustrate some of the forms assumed by native silica.*

Here also is arranged the large collection of Meteorites, the completeness of which is one of the features of this Department of the Museum and which is described in a special guide.† Among these the large mass of meteoric iron, weighing three and a half tons, found about 1854 at Cranbourne, in Australia, and presented to the Museum in 1862 by James Bruce, Esq., is conspicuous.

In addition to the two guides mentioned above, there is published for the use of the student of mineralogy a separate and complete Index to the names and synonyms of all the mineral species and varieties represented in the Collection.‡

SECOND FLOOR.

The upper floor of the East wing is devoted entirely to the Department of Botany.

The Collections of this Department consist of two portions, the one set apart for the use of persons engaged in the scientific study of plants; the other open to the public and consisting of specimens suitable for exhibition, and intended to illustrate the various groups of the Vegetable Kingdom, and the broad facts on which the Natural System of the classification of plants is based.

The portion devoted to the use of the scientific student con-

* A Descriptive Catalogue of the specimens in this case has been printed by Mr. Ruskin, and can be obtained of the attendant in the gallery.
† 'An Introduction to the Study of Meteorites,' with a list of the Meteorites represented in the Collection. Price twopence.
‡ 'The Student's Index to the Collection of Minerals.' Price twopence.
sists mainly of the great Herbarium. This is a collection of plants, fastened on single sheets of folio paper, representing, as far as it has been possible to obtain them, first, every species of plant living on the earth, and then the distribution of each species on the surface of the earth. The various species are collected under their respective genera, and these are arranged in their Natural Orders, and the whole are systematically classified, beginning with the most highly organised (the Ranunculaceae), and going down to the lowest members of the Vegetable Kingdom (the Fungi).

The foundation of this great Herbarium was the collection of Sir Joseph Banks, consisting of the plants obtained by himself and Dr. Solander in their voyage round the world with Captain Cook, and of numerous series from all quarters of the globe presented to him or purchased by him. He bequeathed all his botanical collections to the Trustees of the British Museum in 1820, reserving to Robert Brown, in whose charge they had been for years, the use of them during his lifetime. Mr. Brown transferred them to the Trustees of the Museum in 1827, and was appointed the first Keeper of the Department. The yearly additions since 1827 have been so extensive that the Banksian Collections form now but a small proportion of the great Herbarium. In a brief notice it is impossible to give a correct idea of the richness of this Herbarium. Among the principal collections contained in it may be mentioned those of Clayton, Roemer, Miller, Brown, Bowie and Cunningham, Gardner, Nuttall, Horsfield, König, Martin, Masson, Wilson, Hampe, Seemann, Welwitsch, Salt, and Miers. It includes also authentic specimens received from Loureiro, Gronovius, Tournefort, Jacquin, Aublet, Ruiz and Pavon, and Perrottet.

The cellular plants are accommodated in a large room in the Central Tower approached by a staircase, the entrance to which is on the left side of the statue of Sir Joseph Banks. The Mosses include the collections of Wilson, Hampe, Drummond and Spruce; the Liverworts contain the herbarium of Hampe; with the Lichens are incorporated collections made by Carroll, Spruce and Weddell. The Algae contain the herbarium of Prof. Dickie, the Diatomaceae those of Kützing and Greville, and collections from Harvey, Robert Brown, Shuttleworth, &c.
The extensive series of Fungi, including collections from various botanists, has been lately increased by the bequest of the valuable herbarium of the late C. E. Broome, Esq.

There is a separate Herbarium of British plants, based on the collections formed by Sowerby in the preparation of his great work, 'English Botany.' This is, perhaps, the largest and most interesting public Herbarium of British plants, and its value is constantly increasing by additions from botanists who make the British Flora their special study.

The extensive Herbarium formed by Sir Hans Sloane became the property of the nation in 1753, along with his other collections. The plants gathered by himself in Jamaica form the nucleus of this Herbarium, and added to them are the collections of Petiver, Buddle, Plukenet, Kaempfer, Kamel, Merrett, Boerhaave, Vaillant, Banister, and others. According to the practice of the time these plants are preserved in large folio volumes, of which there are altogether 310. This collection had been placed in the library of the British Museum, and remained there until the establishment of the Department of Botany, when it was transferred to the care of Mr. Brown. The plants are well preserved, and are catalogued in a copy of Ray's 'Historia Plantarum,' so that they can be easily consulted.

The collections formed by Hermann in Ceylon, from which Linnaeus prepared his 'Flora Zeylonica,' are preserved in five volumes, four containing plants, and the fifth consisting of drawings.

The department also contains the singularly interesting and valuable collection of plants gathered in 1663 by John Ray in his travels in Europe, a catalogue of which was published in his account of the journey in 1673.

In these various Herbaria the Museum possesses an unrivalled series of historical collections from the middle of the seventeenth century to the present time.

Besides the collection of dried plants forming the Herbarium, there are two allied collections arranged in the same gallery in parallel series. The one is the collection of fruits and seeds occupying the table cabinets in the centre of the gallery, and the other the collection of woods placed in the smaller cabinets in the centre of each bay. The position of the cabinets has permitted the arrangement of the specimens belonging to these
two collections in close proximity to the Natural Orders in the great Herbarium, to which they belong. The student can thus easily command the specimens in the three collections in the prosecution of his investigations. Nor is the facility of reference confined to the mounted and finally arranged specimens, for the method in which the unmounted collections are arranged and temporarily stored in small rooms behind the great Herbarium provides for their ready consultation, even before they are incorporated into the Herbarium itself.

The student receives assistance in his investigations from the extensive Library of the Department, and from a large collection of plates and drawings of plants systematically arranged in the same order as the plants in the Herbarium.

The collection of original drawings comprises specimens of the work of the principal botanical artists, such as Ehret, J. Miller, Nodder, Aubriet, Sidney Parkinson, J. R. & G. Forster, Jacquin, Masson, Sowerby, Fitch, Schleiden, W. G. Smith, and especially Francis and Ferdinand Bauer.

The department possesses also many valuable manuscripts, such as those of Robert Brown, Solander, Ruiz and Pavon, König, Salisbury, and Miers, referring to plants now in the Herbarium on which these botanists have worked.

The arrangement of the collections in the public gallery is now in progress, but is not sufficiently advanced to permit the preparation of a guide to the cases. A general account of the plan being followed in this arrangement, and of the principal specimens, is all that can now be attempted.

The natural system of classification, according to which the plants in the Herbarium are arranged, is followed in the exhibition cases in the public gallery. A half case next to the door on the left side is devoted to a series of original drawings and specimens exhibiting the principal fungal parasites of cultivated plants. The series of specimens begins in the next case with the Natural Order Ranunculaceae, and the principal orders are represented in this and the following cases by dried specimens of the plants themselves, coloured drawings, fruits, and prepared sections of the woods. Diagrams are employed to emphasise the characters on which the grouping is based. The use of the same colour for the homologous structures throughout the
diagrams readily conveys to the eye the points of agreement and difference on which the classification rests. The geological history of each Natural Order is indicated on a table of the earth's strata; and its present distribution on the surface of the earth is given on a small map of the world. Descriptive labels give particular information respecting each specimen.

Dicotyledonous plants occupy three cases on the left side of the gallery, and are followed by the Monocotyledonous Orders, which fill the last case on the same side, the two half cases at the end of the gallery, and the first case returning towards the door. The Gymnosperms are placed in the next case. Then follow the Cryptogams, a case being devoted to the higher vascular Orders, and another to the lower division of cellular plants. The series closes with an interesting collection of models of the larger British Fungi prepared by Sowerby when he was engaged on his work on this group of plants.

The larger specimens are placed in the tall cases in the centre of the gallery following the order as far as possible of the specimens in the wall-cases. The right side of the first centre case is filled with specimens of Dicotyledonous plants, such as sections of White Oak and Walnut from Canada, of Eucalyptus, Acacia, Laportea, and other trees from Australia, of the Cork Oak grown in Chelsea Gardens, trunks of Ficus and Carallia with aerial roots, sent from Ceylon by Dr. Trimen, stems of Bombax and Xanthoxylon with conical prickles, and of Flacourtia and Gleditschia with branching thorns, and anomalous stems of Bauhinia, Entada, and Dypsis. The next two centre cases are filled with Monocotyledonous plants, among which in the first case are stems and sections of the Date palm, several species of Areca, sections and fruit of the Palmyra palm, stem and fruit of the Sago palm, and a large spike of the allied Raphia from Madagascar. In the next case are stems of the Wax palm, sections and fruit of the Cocoa-nut palm, and of the Seychelles palm. The remainder of this case is occupied with specimens of the Dragon-tree of Madeira, of the Grass-trees and Black-boys of Australia, of Vellozia from Brazil, of Papyrus from Egypt, of Bamboo and Sugar-cane. On the other side of this case specimens of Gymnosperms will be found, comprising a large plant of Welwitschia from Africa, sections of Araucaria
from Norfolk Island, of Cedar grown in Chelsea Gardens, and stems and sections of several species of Cycadeae. The next two cases contain specimens of Tree-ferns, among which are a large stem of Dicksonia, clothed with aerial roots, from New Zealand, stems of species of Alsophila and Cyathea from various tropical regions, and of Hemitelia from South Africa.

REGULATIONS FOR THE ADMISSION OF STUDENTS.

1. The Exhibition Galleries and Study Collections are open to Students every day of the week except Sunday, and except Good Friday, Christmas Day, and any Fast or Thanksgiving Day appointed by authority.

2. The hours for the Exhibition Galleries are throughout the year from ten in the morning—in January, February, November, and December till four; in March, September, and October till five; and in April, May, June, July, and August till six.

3. The hours for the Study Collections are throughout the year from ten till four o'clock.

4. Persons desiring special facilities for study or drawing in the Exhibition Galleries, or admission to the Study Collections, must apply in writing to the Director of the Museum for a Student's ticket, specifying the profession or business, and place of abode of the applicant, and the Department of the Museum to which admission is required.

5. Every such application must be made two days, at least, before admission is required, and must be accompanied by a written recommendation from a householder (whose address can be identified from the ordinary sources of reference), or a person of known position, with full signature and address, stated to be given on personal knowledge of the applicant, and certifying that he or she will make proper use of the department of Natural History to which such admission is required.

6. If such application or recommendation be unsatisfactory, the Director will either refuse admission, or submit the case to the Trustees for their decision.

7. Tickets of Admission must be produced if required, and are not transferable.

8. The privilege of admission is granted upon the following conditions:—

   (a) That it may be at any time suspended by the Director.

   (b) That it may be at any time withdrawn by the Trustees in their absolute discretion.

9. All communications respecting the Departments of Natural History must be addressed to—

   THE DIRECTOR,
   BRITISH MUSEUM (NATURAL HISTORY)
   CROMWELL ROAD
   LONDON, S.W.

By Order of the Trustees, May 22, 1886.
LONDON:
PRINTED BY WILLIAM CLOWES AND SONS, LIMITED,
STAMFORD STREET AND CHARING CROSS.
BRITISH MUSEUM
(NATURAL HISTORY).

DAYS AND HOURS OF ADMISSION.

The Exhibition Galleries are open to the Public, free, every day of the week, except Sunday, in

January and February, from 10 a.m. till 4 p.m.
March, " " " " 5 "
April to August, " " " " 6 "
September and October, " " " " 5 "
November and December, " " " " 4 "

Also, from May 1st to July 16th, on Mondays and Saturdays only, till 8 p.m.,

and from July 18th to August 29th, on Mondays and Saturdays only, till 7 p.m.

The Museum is closed on Good-Friday and Christmas-Day.

By Order of the Trustees,

W. H. FLOWER,
Director.
